

# Socket Programming in Python

## Socket Basics

A *network socket* is an endpoint of an inter-process communication flow across a computer network. Sockets may communicate within a process, between processes on the same machine, or between processes on different continents. Today, most communication between computers is based on the internet protocol; therefore most network sockets are *internet sockets*. To create a connection between machines, Python programs import the **socket** module, create a socket object, and call the object's methods to establish connections and send and receive data. Sockets are the endpoints of a bidirectional communications channel.

## Socket in Python

Python provides two levels of access to network services. At a *low level*, you can access the basic socket support in the underlying operating system, which allows you to implement clients and servers for both connection-oriented and connectionless protocols. Python also has libraries that provide *higher level* access to specific application level network protocols, such as FTP, HTTP, SMTP, and so on.

Sockets may be implemented over a number of different channel types: UNIX domain sockets, TCP, UDP, and so on. The socket library provides specific classes for handling the common transports as well as a generic interface for handling the rest.

## Vocabulary of Sockets

Term	Description
<b>domain</b>	The family of protocols that will be used as the transport mechanism. These values are constants such as <b>AF_INET</b> , <b>PF_INET</b> , <b>PF_UNIX</b> , <b>PF_X25</b> , and so on.
<b>type</b>	The type of communications between the two endpoints, typically <b>SOCK_STREAM</b> for connection-oriented protocols and <b>SOCK_DGRAM</b> for connectionless protocols.
<b>protocol</b>	Typically zero, this may be used to identify a variant of a protocol within a domain and type.
<b>hostname</b>	The identifier of a network interface: <ul style="list-style-type: none"><li>• A string, which can be a host name, a dotted-quad address, or an IPV6 address in colon (and possibly dot) notation</li><li>• A string "<b>&lt;broadcast&gt;</b>", which specifies an <b>INADDR_BROADCAST</b> address.</li><li>• A zero-length string, which specifies <b>INADDR_ANY</b>, or</li><li>• An Integer, interpreted as a binary address in host byte order.</li></ul>
<b>port</b>	Each server listens for clients calling on one or more ports. A port may be a Fixnum port number, a string containing a port number, or the name of a service.

## The *socket* Module

To create a socket, you must use the *socket.socket()* function available in *socket* module, which has the general syntax:

```
s = socket.socket (socket_family, socket_type, protocol=0)
```

Here is the description of the parameters:

- **socket\_family:** This is either AF\_UNIX or AF\_INET, as explained earlier.
- **socket\_type:** This is either SOCK\_STREAM or SOCK\_DGRAM.
- **protocol:** This is usually left out, defaulting to 0.

Once you have *socket* object, then you can use required functions to create your client or server program.

### Server Socket Methods

Method	Description
<b>s.bind()</b>	This method binds address (hostname, port number pair) to socket.
<b>s.listen()</b>	This method sets up and start TCP listener.
<b>s.accept()</b>	This passively accept TCP client connection, waiting until connection arrives (blocking).

### Client Socket Methods

Method	Description
<b>s.connect()</b>	This method actively initiates TCP server connection.

### General Socket Methods

Method	Description
<b>s.recv()</b>	This method receives TCP message
<b>s.send()</b>	This method transmits TCP message
<b>s.recvfrom()</b>	This method receives UDP message
<b>s.sendto()</b>	This method transmits UDP message
<b>s.close()</b>	This method closes socket
<b>socket.gethostname()</b>	Returns the hostname.

### A Simple Server

To write Internet servers, we use the **socket** function available in socket module to create a socket object. A socket object is then used to call other functions to setup a socket server.

Now call **bind(hostname, port)** function to specify a *port* for your service on the given host.

Next, call the *accept* method of the returned object. This method waits until a client connects to the port you specified, and then returns a *connection* object that represents the connection to that client.

```
#!C:\Python33\python.exe
# Echo server program
import socket
host = socket.gethostname()
port = 12345
s = socket.socket()
s.bind((host, port))
s.listen(5)
conn, addr = s.accept()
print('Got connection from ', addr[0], '(', addr[1], ')')
print('Thank you for connecting')
while True:
    data = conn.recv(1024)
    if not data: break
    conn.sendall(data)
conn.close()
```

## A Simple Client

Now we will write a very simple client program which will open a connection to a given port 12345 and given host. This is very simple to create a socket client using Python's *socket* module function.

The `socket.connect(hostname, port)` opens a TCP connection to *hostname* on the *port*. Once you have a socket open, you can read from it like any IO object. When done, remember to close it, as you would close a file.

The following code is a very simple client that connects to a given host and port, reads any available data from the socket, and then exits:

```
#!C:\Python33\python.exe
# Echo client program
import socket
host = socket.gethostname()
port = 12345
s = socket.socket()
s.connect((host, port))
s.sendall(b'Welcome User!')
data = s.recv(1024)
s.close()
print(repr(data))
```

Now run this *server.py* in background and then run above *client.py* to see the result.

### ***Output:***

Step 1: Run *server.py*. It would start a server in background.

Step 2: Run *client.py*. Once server is started run client.

Step 3: Output of *server.py* generates as follows:

```
C:\Users\Ashok Kumar\Desktop>python server.py
Got connection from 192.168.3.21 ( 61428 )
Thank you for connecting
```

Step 4: Output of *client.py* generates as follows:

```
C:\Users\Ashok Kumar\Desktop>python clients.py
b'Welcome User!'
```

## Python Internet Modules

A list of some important modules which could be used in Python Network/Internet programming.

Protocol	Common function	Port No	Python module
<b>HTTP</b>	Web pages	80	httplib, urllib, xmlrpclib
<b>NNTP</b>	Usenet news	119	nntplib
<b>FTP</b>	File transfers	20	ftplib, urllib
<b>SMTP</b>	Sending email	25	smtplib
<b>POP3</b>	Fetching email	110	poplib
<b>IMAP4</b>	Fetching email	143	imaplib
<b>Telnet</b>	Command lines	23	telnetlib
<b>Gopher</b>	Document transfers	70	gopherlib, urllib
